11.1 Asynchronous Programming with Callbacks

JavaScript – The language of the Web

# CALLBACKS

# Callbacks

- A callback function is a function passed into another function as an argument, which is then invoked inside the outer function to complete some kind of routine or action.
  - Synchronous
  - Asynchronous

```
function logQuote(quote) {
  console.log(quote);
}

function createQuote(quote,
  callback) {
  const myQuote = `Like I always
say, '${quote}'`;
  callback(myQuote);
}

createQuote("WebApp I rocks!",
  logQuote);
```

# Synchronous Callbacks

- Used in functional programming
  - e.g., providing the sort criteria for array sorting

```
let numbers = [4, 2, 5, 1, 3];  
  
numbers.sort(function(a, b) {  
  return a - b;  
});  
  
console.log(numbers);
```

```
let numbers = [4, 2, 5, 1, 3];  
  
numbers.sort((a, b) => a - b);  
  
console.log(numbers);
```

# Synchronous Callbacks

- Example: filter according to a criteria
  - filter() creates a **new** array with all elements for which the callback returns true

```
const market = [  
  { name: 'GOOG', var: -3.2 },  
  { name: 'AMZN', var: 2.2 },  
  { name: 'MSFT', var: -1.8 }  
];  
  
const bad = market.filter(stock => stock.var < 0);  
// [ { name: 'GOOG', var: -3.2 }, { name: 'MSFT', var: -1.8 } ]  
  
const good = market.filter(stock => stock.var > 0);  
// [ { name: 'AMZN', var: 2.2 } ]
```

JavaScript: The Definitive Guide, 7th Edition  
Chapter 6. Array  
Chapter 7.8 Functional Programming

JavaScript – The language of the Web

# FUNCTIONAL PROGRAMMING

# Functional Programming: A Brief Overview

- A programming paradigm where the developer mostly construct and structure code using *functions*
  - not JavaScript's main paradigm, but JavaScript is well suited
- More “declarative stile” rather than “imperative style” (e.g., for loops)
- Can improve program readability:

```
new_array =  
  array.filter ( filter_function ) ;
```

```
new_array = [] ;  
for (const el in list)  
  if ( filter_function(el) )  
    new_array.push(el) ;
```

# Notable Features of the Functional Paradigm

- Functions are *first-class* citizens
  - functions can be used as if they were variables or constants, combined with other functions and generate new functions in the process, chained with other functions, etc.
- *Higher-order functions*
  - a function that operates on functions, taking one or more functions as arguments and typically returning a new function
- Function *composition*
  - composing/creating functions to simplify and compress your functions by taking functions as an argument and return an output
- Call *chaining*
  - returning a result of the same type of the argument, so that multiple functional operators may be applied consecutively

# Functional Programming in JavaScript

- JavaScript supports the features of the paradigm “out of the box”
- Functional programming requires *avoiding mutability*
  - i.e., do not change objects in place!
  - e.g., if you need to perform a change in an array, return a new array

# Iterating over Arrays

- Iterators: `for ... of`, `for (...;...;...)`
- Iterators: `forEach(f)`
  - Process each element with callback `f`
- Iterators: `every(f)`, `some(f)`
  - Check whether all/some elements in the array satisfy the Boolean callback `f`
- Iterators that return a new array: `map(f)`, `filter(f)`
  - Construct a new array
- **reduce**: callback function on all items to *progressively* compute a result  
`reduce(callback( accumulator, currentValue[, index[, array]] )[, initialValue])`

# .forEach()

- `forEach()` invokes your (synchronous) callback function once for each element of an **iterable**

```
const letters = [..."Hello world"] ;
let uppercase = "" ;
letters.forEach(letter => {
  uppercase += letter.toUpperCase();
});
console.log(uppercase); // HELLO WORLD
```

# .forEach()

- `forEach()` invokes your (synchronous) callback function once for each element of an **iterable**
  - The callback may have 3 parameters
    - `currentValue`: The current element being processed in the array.
    - `index` (Optional): The index of `currentValue` in the array
    - `array` (Optional): The array `forEach()` was called upon.
  - Always **returns *undefined*** and is **not chainable**
  - No way to stop or break a `forEach()` loop other than by throwing an exception
- `forEach()` does not mutate the array on which it is called
  - however, its callback *may* do so

# .every()

- `every()` tests whether **all elements** in the array pass the test implemented by the provided function
  - Callback: Same 3 arguments as `forEach`
  - It returns a Boolean value (*truthy/falsy*)
  - It executes its callback once for each element present in the array until it finds the one where the callback returns a falsy value
    - If such an element is found, **immediately** returns false

```
let a = [1, 2, 3, 4, 5];  
a.every(x => x < 10); // => true: all values are < 10  
a.every(x => x % 2 === 0); // false: not all even values
```

# .some()

- `some()` tests whether **at least one** element in the array passes the test implemented by the provided function
  - It returns a Boolean value
  - It executes its callback once for each element present in the array until it finds the one where the callback returns a truthy value
    - if such an element is found, **immediately** returns true

```
let a = [1, 2, 3, 4, 5];  
a.some(x => x%2===0); // => true; a has some even numbers  
a.some(isNaN);
```

# .map()

- `map()` passes each element of the **array** on which it is invoked to the function you specify
  - the callback should return a value
  - `map()` always returns a **new array** containing the values returned by the callback

```
const a = [1, 2, 3];  
  
const b = a.map(x => x*x);  
  
console.log(b); // [1, 4, 9]
```

```
const letters = [..."Hello world"];  
  
const uppercase = letters.map(letter  
=> letter.toUpperCase());  
  
console.log(uppercase.join(''));
```

# .filter()

- `filter()` creates a **new array** with all elements that pass the test implemented by the provided function
  - the callback is a function that returns either true or false
  - if no element passes the test, an empty array is returned

```
const a = [5, 4, 3, 2, 1];  
  
a.filter(x => x < 3); // generates [2, 1], values less than 3  
  
a.filter((element, index) => index%2 == 0); // [5, 3, 1]
```

# .reduce()

```
reduce(  
    callback(accumulator, currentValue[, index[, array]])  
    [, initialValue]  
)
```

- `reduce()` combines the elements of an **array**, using the specified function, to produce a ***single value***
  - this is a common operation in functional programming and goes by the names “inject” and “fold”
- `reduce` takes two arguments:
  1. the “*reducer function*” (`callback`) that performs the reduction/combination operation (combine or **reduce 2 values into 1**)
  2. an (optional) **initialValue** to pass to the function; if not specified, it uses the first element of the array as initial value

# .reduce()

- Callbacks used with `reduce()` are different than the ones used with `forEach()` and `map()`
  - the *first* argument is the **accumulated result** of the reduction so far
  - on the first call to this function, its first argument is the initial value
  - on subsequent calls, it is the value returned by the previous invocation of the reducer function

```
const a = [5, 4, 3, 2, 1];

a.reduce( (accumulator, currentValue) =>
accumulator + currentValue, 0);
// 15; the sum of the values

a.reduce((acc, val) => acc*val, 1);
// 120; the product of the values

a.reduce((acc, val) => (acc > val) ? acc
: val);
// 5; the largest of the values
```

# Example: average price of all SUVs

```
const vehicles = [  
  { make: 'Honda', model: 'CR-V', type: 'suv', price: 24045 },  
  { make: 'Honda', model: 'Accord', type: 'sedan', price: 22455 },  
  { make: 'Mazda', model: 'Mazda 6', type: 'sedan', price: 24195 },  
  { make: 'Mazda', model: 'CX-9', type: 'suv', price: 31520 },  
  { make: 'Toyota', model: '4Runner', type: 'suv', price: 34210 },  
  { make: 'Toyota', model: 'Sequoia', type: 'suv', price: 45560 },  
  { make: 'Toyota', model: 'Tacoma', type: 'truck', price: 24320 },  
  { make: 'Ford', model: 'F-150', type: 'truck', price: 27110 },  
  { make: 'Ford', model: 'Fusion', type: 'sedan', price: 22120 },  
  { make: 'Ford', model: 'Explorer', type: 'suv', price: 31660 }  
];
```

```
const averageSUVPrice = vehicles  
  .filter(v => v.type === 'suv')  
  .map(v => v.price)  
  .reduce( (sum, price, i, array) => sum + price / array.length, 0);
```

```
console.log(averageSUVPrice); // 33399
```

JavaScript – The language of the Web

# ASYNCHRONOUS PROGRAMMING

# Asynchronicity

- JavaScript is single-threaded and inherently synchronous
  - i.e., code cannot create threads and run in parallel in the JS engine
- Callbacks are the most fundamental way for writing asynchronous JS code
- How can they work asynchronously?
  - e.g., how can `setTimeout()` or other async callbacks work?
- Thanks to the Execution Environment
  - e.g., browsers and Node.js
- and the Event Loop

```
const deleteAfterTimeout = (task) =>
{
  // do something
}
// runs after 2 seconds
setTimeout(deleteAfterTimeout, 2000,
task)
```

# Non-Blocking Code!

- Asynchronous techniques are very useful, particularly for web development
- For instance: when a web app runs executes an intensive chunk of code without returning control to the browser, the browser can appear to be frozen
  - this is called blocking, and it should be the exception!
    - the browser is blocked from continuing to handle user input and perform other tasks until the web app returns control of the processor
- This may happen outside browsers, as well
  - e.g., reading a long file from the disk/network, accessing a database and returning data, accessing a video stream from a webcam, etc.
- Most of the JS execution environments are, therefore, deeply asynchronous
  - with non-blocking primitives
  - JavaScript programs are event-driven, typically

# Asynchronous Callbacks

- The most fundamental way for writing asynchronous JS code
- Great for “simple” things!
- Handling user actions
  - e.g., button click
- Handling I/O operations
  - e.g., fetch a document
- Handling time intervals
  - e.g., timers
- Interfacing with databases

```
const readline = require('readline');

const rl = readline.createInterface({
  input: process.stdin,
  output: process.stdout
});

rl.question('How old are you? ', (answer) => {
  let description = answer;

  rl.close();
});
```

# Timers

- Useful to delay the execution of a function. Two possibilities from the runtime environment
  - `setTimeout()` runs the callback function after a given period of time
  - `setInterval()` runs the callback function periodically

```
const onesec = setTimeout(()=> {  
    console.log('hey') ; // after 1s  
}, 1000) ;
```

```
console.log('hi') ;
```

Note: timeout value in ms,  $< 2^{31}-1$  (about 24 days)

```
const myFunction = (firstParam,  
secondParam) => {  
    // do something  
}  
// runs after 2 seconds  
setTimeout(myFunction, 2000,  
firstParam, secondParam) ;
```

# Timers

- `clearInterval()`: for stopping the periodical invocation of `setInterval`

```
const id = setInterval(() => {}, 2000) ;  
// «id» is a handle that refers to the timer  
  
clearInterval(id) ;
```

# Handling Errors in Callbacks

- No “official” ways, only best practices!
- Typically, the first parameter of the callback function is for storing any error, while the second one is for the result of the operation
  - this is the strategy adopted by Node.js, for instance

```
fs.readFile('/file.json', (err, data) => {  
  if (err !== null) {  
    console.log(err);  
    return;  
  }  
  //no errors, process data  
  console.log(data);  
});
```

Data Persistence

# **DATABASE ACCESS WITH SQLITE**

# Server-Side Persistence

- A web server should normally store data into a persistent database
- Node supports most databases
  - Cassandra, Couchbase, CouchDB, LevelDB, MySQL, MongoDB, Neo4j, Oracle, PostgreSQL, Redis, SQL Server, SQLite, Elasticsearch
- An easy solution for simple and small-volume applications is **SQLite**
  - in-process on-file relational database

# SQLite

- Uses the 'sqlite' npm module
- Documentation: <https://github.com/mapbox/node-sqlite3/wiki>

```
npm install sqlite3
```

```
const sqlite = require('sqlite3');  
const db = new sqlite.Database('exams.sqlite', // DB filename  
  (err) => { if (err) throw err; });  
  
...  
db.close();
```

# SQLite: Queries

```
rows.forEach((row) => {  
    console.log(row.name);  
});
```

- `const sql = "SELECT...";`
- `db.all(sql, [params], (err, rows) => { } )`
  - Executes sql and **returns all the rows** in the callback
  - If err is true, some error occurred. Otherwise, **rows** contains the result
  - **rows** is an array. Each item contains the fields of the result

<https://www.sqlitetutorial.net/sqlite-nodejs/>

# SQLite: Queries

```
rows.forEach((row) => {  
    console.log(row.name);  
});
```

- `db.get(sql, [params], (err, row) => { } )`
  - Get only **the first row** of the result (e.g., when the result has 0 or 1 elements: primary key queries, aggregate functions, ...)
- `db.each(sql, [params], (err, row) => { } )`
  - Executes the callback **once per each result row** (no need to store all of them)

<https://www.sqlitetutorial.net/sqlite-nodejs/>

# SQLite: Other Queries

- `db.run(sql, [params], (err) => { } )`
  - For statement that do not return a value
  - CREATE TABLE
  - INSERT
  - UPDATE
  - In the callback function
    - `this.changes` == number of affected rows
    - `this.lastID` == number of inserted row ID (for INSERT queries)

# Parametric Queries

- The SQL string may contain parameter placeholders: ?
- The placeholders are replaced by the values in the [params] array
  - in order: one param per each ?

```
const sql = 'SELECT * FROM course WHERE code=?';  
db.get(sql, [code], (err, row) => {
```

- Always use parametric queries – never string+concatenation nor  
`template strings`

# Example

Table: course

	code	name	CFU

for(let i=0; i<100; i++) {
  db.run('insert into numbers(number) values(1)',
    (err) => { if (err) throw err; });

  db.all('select count(*) as tot from numbers',
    (err, rows) => {
      if(err) throw err;
      console.log(rows[0].tot);
    });
}
db.close();
```

# Solution?

```
for(let i=0; i<100; i++) {  
  db.run('insert into numbers(number) values(1)',  
    (err) => { if (err) throw err;  
              else  });  
  db.all('select count(*) as tot from numbers',  
    (err, rows) => {  
      if(err) throw err;  
      console.log(rows[0].tot);  
        
    });  
}
```

A possible solution is in `queries_sync.js`, but it's **not** recommended

# PROMISES

# Beware: *Callback Hell!*

- If you want to perform multiple asynchronous actions in a row using callbacks, you must keep passing new functions to handle the continuation of the computation after the previous action
  - every callback adds a level of nesting
  - when you have lots of callbacks, the code starts to be complicated very quickly

```
const readline = require('readline');
const rl = readline.createInterface(...);

rl.question('Task description: ', (answer) => {
  let description = answer;

  rl.question('Is the task important? (y/n)', (answer) => {
    let important = answer;

    rl.question('Is the task private? (y/n)', (answer) => {
      let private = answer;

      rl.question('Task deadline: ', (answer) => {
        let date = answer;
        ...
      }
    }
  }
});

rl.close();
});
```

# Promises

- A core language feature to “**simplify**” **asynchronous programming**
  - a possible solution to callback hell, too!
  - a fundamental building block for “newer” functions (async, ES2017)
- It is an **object** representing the **eventual completion** (or **failure**) of an asynchronous operation
  - i.e., an asynchronous function returns *a promise to supply the value* at some point in the future, instead of returning immediately a final value
- Promises standardize a way to handle errors and provide a way for errors to propagate correctly through a chain of promises

# Promises

- Promises can be created or consumed
  - many Web APIs expose Promises to be consumed!
- When consumed:
  - a Promise starts in a pending state
    - the caller function continues the execution, while it waits for the Promise to do its own processing, and give the caller function some “responses”
  - then, the caller function waits for it to either return the promise in a fulfilled state or in a rejected state

# Creating a Promise

- A Promise object is created using the **new** keyword
- Its constructor takes an *executor function*, as its parameter
- This function takes two *functions* as parameters:
  - **resolve**, called when the asynchronous task completes successfully and returns the results of the task as a value
  - **reject**, called when the task fails and returns the reason for failure (an error object, typically)

```
const myPromise =
  new Promise((resolve, reject) => {

    // do something asynchronous which
    eventually call either:

        resolve(someValue); // fulfilled

    // or

        reject("failure reason"); // rejected

  });
```

# Creating a Promise

- You can also provide a function with “promise functionality”
- Simply have it return a promise!

```
function wait(duration) {  
  // Create and return a new promise  
  return new Promise((resolve, reject) => {  
    // If the argument is invalid,  
    // reject the promise  
    if (duration < 0) {  
      reject(new Error('Time travel not yet  
implemented'));  
    } else {  
      // otherwise, wait asynchronously and then  
      // resolve the Promise; setTimeout will  
      // invoke resolve() with no arguments:  
      // the Promise will fulfill with  
      // the undefined value  
      setTimeout(resolve, duration);  
    }  
  });  
}
```

# Consuming a Promise

- When a Promise is **fulfilled**, the **then()** callback is used
- If a Promise is **rejected**, instead, the **catch()** callback will handle the error
- **then()** and **catch()** are instance methods defined by the Promise object
  - each function registered with **then()** is invoked only once
- You can omit **catch()**, if you are interested in the result, only

```
waitPromise().then((result) => {
    console.log("Success: ", result);
}).catch((error) => {
    console.log("Error: ", error);
});

// if a function returns a Promise...
wait(1000).then(() => {
    console.log("Success!");
}).catch((error) => {
    console.log("Error: ", error);
});
```

# Consuming a Promise

- `p.then(onFulfilled[, onRejected]);`
  - Callbacks are executed asynchronously (inserted in the event loop) when the promise is either fulfilled (success) or rejected (optional)
- `p.catch(onRejected);`
  - Callback is executed asynchronously (inserted in the event loop) when the promise is rejected
- `p.finally(onFinally);`
  - Callback is executed in any case, when the promise is either fulfilled or rejected.
  - Useful to avoid code duplication in then and catch handlers
- All these methods return **Promises**, too!  $\Rightarrow$  They can be **chained**

# Promise: Create & Consume

```
const prom = new Promise(  
  (resolve, reject) => {  
    ...  
    resolve(x);  
    ...  
    reject(y);  
    ...  
  }  
)
```

```
prom  
  .then((x) => {  
    ...use x...  
  } )  
  .catch( (y) => {  
    ...use y...  
  } ) ;
```

# Chaining Promises

- One of the most important benefits of Promises
- They provide a natural way to express a sequence of asynchronous operations as a **linear chain of `then()`** invocations
  - **without having to nest** each operation within the callback of the previous one
    - the "callback hell" seen before
- **Important:** always return results, otherwise callbacks won't get the result of a previous promise

```
getRepoInfo()
  .then(repo => getIssue(repo))
  .then(issue => getOwner(issue.ownerId))
  .then(owner => sendEmail(owner.email,
'Some text'))
  .catch(e => {
    // just log the error
    console.error(e)
  })
  .finally(_ => logAction());
});
```

# Example: Chaining

- Useful, for instance, with I/O API such as `fetch()`, which returns a Promise

```
const status = (response) => {
  if (response.status >= 200 && response.status < 300) {
    return Promise.resolve(response) // static method to return a fulfilled Promise
  }
  return Promise.reject(new Error(response.statusText))
}
const json = (response) => response.json()

fetch('/todos.json')
  .then(status)
  .then(json)
  .then((data) => { console.log('Request succeeded with JSON response', data) })
  .catch((error) => { console.log('Request failed', error) })
```

# Promises... in Parallel

```
Promise.all(promises)
  .then(results => console.log(results))
  .catch(e => console.error(e));
```

- What if we want to execute several asynchronous operations in parallel?
- `Promise.all()`
  - takes an array of Promise objects as its input and returns a Promise
  - the returned Promise will be rejected if at least one of the input Promises is rejected
  - otherwise, it will be fulfilled with an **array of the fulfillment values** for each of the input promises
  - the input array can contain non-Promise values, too: if an element of the array is not a Promise, it is simply copied unchanged into the output array
- `Promise.race()`
  - returns a Promise that is fulfilled or rejected when **the first** of the Promises in the input array is fulfilled or rejected
  - if there are any non-Promise values in the input array, it simply returns the first one

JavaScript – The language of the Web

# ASYNC/AWAIT

# Simplifying Writing With `async` / `await`

- ECMAScript 2017 (**ES8**) introduces two new keywords, **`async`** and **`await`**
  - write promise-based asynchronous code that **looks like** synchronous code
- Prepend the **`async`** keyword to any function means that it will return a Promise
- Prepend **`await`** when calling an `async` function (or a function returning a Promise) makes the calling code stop until the promise is resolved or rejected

```
const sampleFunction = async () => {  
  return 'test'  
}  
sampleFunction().then(console.log) // This will log 'test'
```

# async Functions

- The `async` function declaration defines an asynchronous function
- Asynchronous functions operate in a separate order than the rest of the code (via the event loop), returning an **implicit Promise** as their result
  - but the syntax and structure of code using async functions looks like standard synchronous functions.

```
async function name([param[, param[, ...param]]]) {  
    statements  
}
```

[https://developer.mozilla.org/en-US/docs/Web/JavaScript/Reference/Statements/async\\_function](https://developer.mozilla.org/en-US/docs/Web/JavaScript/Reference/Statements/async_function)

# await

- The `await` operator can be used to wait for a Promise. It can *only be used inside an async function*
- `await` **blocks** the code execution within the async function **until the Promise is resolved**
- When resumed, the value of the `await` expression is that of the fulfilled Promise
- If the Promise is rejected, the `await` expression **throws** the rejected value
  - If the value of the expression following the `await` operator is not a Promise, it's converted to a resolved Promise

```
returnValue = await expression ;
```

<https://developer.mozilla.org/en-US/docs/Web/JavaScript/Reference/Operators/await>

# Example: async / await

```
function resolveAfter2Seconds() {  
  return new Promise(resolve => {  
    setTimeout(() => {  
      resolve('resolved');  
    }, 2000);  
  });  
}  
  
async function asyncCall() {  
  console.log('calling');  
  const result = await resolveAfter2Seconds();  
  console.log(result);  
}  
  
asyncCall();
```

} Return a  
promise

} async is needed to use await

} Looks like  
sequential  
code

```
> "calling"  
//... 2 seconds  
> "resolved"
```

# Example: async / await

```
function resolveAfter2Seconds() {  
  return new Promise(resolve => {  
    setTimeout(() => {  
      resolve('resolved');  
    }, 2000);  
  });  
}  
  
async function asyncCall() {  
  console.log('calling');  
  const result = await resolveAfter2Seconds();  
  return 'end';  
}  
  
asyncCall().then(console.log);
```

} Implicitly returns a Promise

} Can use Promise methods

```
> "calling"  
//... 2 seconds  
> "end"
```

# Examples... Before and After

```
const makeRequest = () => {  
  return getAPIData()  
    .then(data => {  
      console.log(data);  
      return "done";  
    })  
};  
  
let res = makeRequest();
```

```
const makeRequest = async () => {  
  console.log(await getAPIData());  
  return "done";  
};  
  
let res = makeRequest();
```

# Examples... Before and After

```
function getData() {  
  return getIssue()  
    .then(issue => getOwner(issue.ownerId))  
    .then(owner => sendEmail(owner.email, 'Some text'));  
}
```

// assuming that all the 3 functions above return a Promise

```
async function getData = {  
  const issue = await getIssue();  
  const owner = await getOwner(issue.ownerId);  
  await sendEmail(owner.email, 'Some text');  
}
```

# Chaining with async/await

- Simpler to read, easier to debug
  - debugger would not stop on asynchronous code

```
const getFirstUserData = async () => {  
  const response = await fetch('/users.json'); // get users list  
  const users = await response.json(); // parse JSON  
  const user = users[0]; // pick first user  
  const userResponse = await fetch(`/users/${user.name}`); // get user data  
  const userData = await user.json(); // parse JSON  
  return userData;  
}  
getFirstUserData();
```

# Promises or async/await? Both!

- If the output of `function2` is dependent on the output of `function1`, use `await`.
- If two functions can be run in parallel, create two different async functions and then run them in parallel `Promise.all(promisesArray)`
- Instead of creating huge async functions with many `await asyncFunction()` in it, it is better to create **smaller** async functions (not too much blocking code)
- If your code contains blocking code, it is better to make it an async function. The callers can decide on the level of asynchronicity they want.

# SQLite... revisited

```
async function insertOne() {

# SQLite Libraries: Various Options

- `sqlite3`: the basic SQLite interface (JS wrapper of the SQLite C library)
- `sqlite`: This module has the same API as the original `sqlite3` library, except that all its API methods **return ES6 Promises**.
  - internally, it wraps `sqlite3`; written in TypeScript
- `sqlite-async`: **ES6 Promise-based** interface to the `sqlite3` module.
- `better-sqlite3`: Easy-to-use **synchronous** API (they say it's faster...)
